

Lab: Syntax, Functions and Statements

1. String Length

Write a JS function that takes **three string arguments** as an input.

Calculate the **sum** of the **length** of the **strings** and the **average length** of the strings **rounded down** to the nearest integer.

The **input** comes as **three string arguments** passed to your function.

The **output** should be printed on the console on two lines.

Examples

Input	Output
'chocolate', 'ice cream', 'cake'	22 7

Input	Output
'pasta', '5', '22.3'	10 3

Hints

- Write a function that receives three string arguments.
- Declare two variables named **sumLength** and **averageLength** that will keep the mathematical results.
- Calculate the length of the strings using the **length** property.

```
function solve(arr1, arr2, arr3) {  
    let sumLength;  
    let averageLength;  
  
    let firstArgumentLength = arr1.length;  
    let secondArgumentLength = arr2.length;  
    let thirdArgumentLength = arr3.length;
```

- Calculate the sum of the three lengths.

```
sumLength = firstArgumentLength + secondArgumentLength + thirdArgumentLength;
```
- Calculate the **average length** of the strings **rounded down** to the nearest integer. Use the **Math.floor()** function.

```
averageLength = Math.floor(sumLength / 3);
```

- Print the results on the console.

```
console.log(sumLength);  
console.log(averageLength);
```

What to submit?

Function Signature: `function main(arg1, arg2, arg3)`

2. Math Operations

Write a JS function that takes **two numbers** and a **string** as an input.

The string may be one of the following: `'+', '-', '*', '/', '%', '**'`.

Print on the console the result of the mathematical **operation** between **both numbers** and the **operator** you receive as a string.

The **input** comes as **two numbers** and a **string argument** passed to your function.

The **output** should be printed on the console.

Examples

Input	Output
5, 6, '+'	11

Input	Output
3, 5.5, '*'	16.5

Hints

- Write a function which receives **three** arguments:

```
function solve(num1, num2, operator) {  
  
}
```

- Declare a variable named **result** that will keep your mathematical result.
- Write down **switch** command that will take the string from your input and depending on it, perform the mathematical logic between the two numbers.

```
function solve(num1, num2, operator) {  
  
    let result;  
    switch (operator) {  
        case '+': result = num1+num2; break;  
        case '-': result = num1-num2; break;  
        case '/': result = num1/num2; break;  
        case '*': result = num1*num2; break;  
        case '%': result = num1%num2; break;  
        case '**': result = num1**num2; break;  
    }  
    console.log(result);  
}
```

- Print the result on the console.

```
console.log(result);
```

What to submit?

Function Signature: `function main(num1, num2, operator)`

3. Sum of Numbers N...M

Write a JS function that takes two numbers **n** and **m** as an input and **prints the sum** of all numbers from **n** to **m**.

The **input** comes as **two string elements** that need to be **parsed** as numbers.

The **output** should **return the sum**.

Examples

Input	Output
'1', '5'	15

Input	Output
'-8', '20'	174

Hints

- Write a function that receives two string arguments and parse them as numbers. Use `Number(string)` function or just put the '+' sign before the string.

```
function solve(n, m) {  
    let num1 = Number(n);  
    let num2 = Number(m);  
}  
  
function solve(n, m) {  
    let num1 = +n;  
    let num2 = +m;  
}
```

- Declare a variable named **result** that will keep the mathematical results.
- Write a **for** loop from **num1** to **num2** and for every turn of the cycle, until it's completed, add the current value.

```
for (let i = num1; i <= num2; i++) {  
    result += i;  
}
```

- Finally, return the result.

```
return result;
```

What to submit?

Function Signature: `function main(n, m)`

4. Largest Number

Write a function that takes **three number arguments** as an input and find the **largest** of them. Print the following text on the console: 'The largest number is {number}.'

The **input** comes as **three number arguments** passed to your function.

The **output** should be printed to the console.

Example

Input	Output
5, -3, 16	The largest number is 16.
Input	Output
-3, -5, -22.5	The largest number is -3.

Hints

- Write a function that receives three number arguments.
 - Declare a variable named **result** that will keep the result.
- ```
function solve(num1, num2, num3) {
 let result;
}
```
- Make several checks to find out the largest of the three numbers. Start with num1.

```
if (num1 > num2 && num1 > num3) {
 result = num1;
}
```

- Do the same for the others.

```
else if (num2 > num1 && num2 > num3) {
 result = num2;
}
else if (num3 > num1 && num3 > num2) {
 result = num3;
}
```

- Print the result on the console.

```
console.log(`The largest number is ${result}.`)
```

### What to submit?

Function Signature: function main(num1, num2, num3)

## 5. Circle Area

Write a function that takes a **single argument** as an input.

**Check the type** of the input argument. If it is a **number**, assume it is the radius of a circle and **calculate the circle area**. Print the **area rounded to two decimal places**.

If the argument type is **NOT** a number, print the following text on the console:

'We cannot calculate the circle area, because we receive a {type of argument}.'

The **input** comes as a **single argument** passed to your function.

The **output** should be printed on the console.

### Example

| Input | Output |
|-------|--------|
| 5     | 78.54  |

| Input  | Output                                                            |
|--------|-------------------------------------------------------------------|
| 'name' | We cannot calculate the circle area, because we receive a string. |

### Hints

- Write a function that receives a single argument.
- Declare a variable named **result** that will keep your result.

```
function solve(input) {
 let result;
}
solve(5);
solve('name');
```

- Check the type of the input argument with the **typeof** operator.

```
let inputType = typeof(input);
```

- If the type is equal to **'number'**, calculate the circle area and print it on the console rounded to two decimal places. To do this, use the method **toFixed()**.

The **Math.pow()** function returns the base to the exponent power, that is, base exponent. You can find more information about the area [here](#):

```
if (inputType === 'number') {
 result = Math.pow(input, 2) * Math.PI;
 console.log(result.toFixed(2));
}
```

- If the type is **NOT** a **'number'**, print the following text on the console:

```
else {
 console.log(`We can not calculate the circle area,
 because we receive a ${inputType}.`)
}
```

## What to submit?

Function Signature: `function main(input)`

## 6. Square of Stars

Write a function that **prints a rectangle** made of **stars** with variable **size**, depending on an input parameter. If there is **no parameter** specified, the rectangle should **always** be of **size 5**. Look at the examples to get an idea.

The **input** comes as a single **number** argument.

The **output** is a series of lines printed on the console, forming a rectangle of variable size.

### Examples

| Input | Output | Input | Output     | Input | Output                                                        | Input | Output                                                                     |
|-------|--------|-------|------------|-------|---------------------------------------------------------------|-------|----------------------------------------------------------------------------|
| 1     | *      | 2     | * *<br>* * | 5     | * * * * *<br>* * * * *<br>* * * * *<br>* * * * *<br>* * * * * | 6     | * * * * *<br>* * * * *<br>* * * * *<br>* * * * *<br>* * * * *<br>* * * * * |

## What to submit?

Function Signature: `function main(num)`

## 7. Day of Week

Write a function that prints a number between 1 and 7 when a **day of the week** is passed to it as a string and an **error message** if the string is **not recognized**.

The **input** comes as a single string argument.

The **output** should be returned as a result.

### Examples

| Input  | Output | Input  | Output | Input   | Output |
|--------|--------|--------|--------|---------|--------|
| Monday | 1      | Friday | 5      | Invalid | error  |

## What to submit?

Function Signature: `function main(day)`

## 8. Aggregate Elements

Write a program that performs different operations on an array of elements. Implement the following operations:

- **Sum( $a_i$ )** - calculates the sum all elements from the input array
- **Sum( $1/a_i$ )** - calculates the sum of the inverse values ( $1/a_i$ ) of all elements from the array
- **Concat( $a_i$ )** - concatenates the string representations of all elements from the array

The **input** comes as an array of number elements.

The **output** should be printed on the console on a new line for each of the operations.

### Examples

| Input     | Output             | Input         | Output                |
|-----------|--------------------|---------------|-----------------------|
| [1, 2, 3] | 6<br>1.8333<br>123 | [2, 4, 8, 16] | 30<br>0.9375<br>24816 |

### What to submit?

Function Signature: `function main(numArray)`

## 9. Words Uppercase

Write a program that **extracts all words** from a passed in string and converts them to **upper case**. The extracted words in upper case must be printed on a single line separated by ", ".

The **input** comes as a single string argument - the text to extract and convert words from.

The **output** should be a single line containing the converted string.

### Examples

| Input              | Output            | Input   | Output |
|--------------------|-------------------|---------|--------|
| 'Hi, how are you?' | HI, HOW, ARE, YOU | 'hello' | HELLO  |

### Hints

- You may need to use a [Regular Expression](#) or alternatively check for all delimiters that can be found in a sentence (ex. ", " , "!", "?" and so on).

### What to submit?

Function Signature: `function main(input)`
